

1 is true for every possible different face model. By adding this constraint, the base
2 mesh has a property in that it fits different face models in the same way. In
3 addition, the inventive algorithm utilizes a smoothing functional that is minimized
4 to ensure that there is a good correspondence between the base mesh and the face
5 model.

6 In another embodiment, a reflectance processing technique is provided that
7 gives a measure of the reflectance of the surface of a subject's face. To measure
8 reflectance, the inventive technique separates the reflectance into its diffuse and
9 specular components and focuses on the treatment of the diffuse components.

10 To measure the diffuse component, an albedo map is first defined. The
11 albedo map is defined by first providing a camera and a subject that is illuminated
12 by multiple different light sources. The light sources are filtered by polarizing
13 filters that, in combination with a polarizing filter placed in front of the camera,
14 suppress specular reflection or prevent specular reflection from being recorded. A
15 sequence of images is taken around the subject's head. Each individual image is
16 processed to provide an individual albedo map that corresponds to that image. All
17 of the albedo maps for a particular subject are then combined to provide a single
18 albedo map for the subject's entire face.

19 20 **BRIEF DESCRIPTION OF THE DRAWINGS**

21 Fig. 1 is a high level diagram of a general purpose computer that is suitable
22 for use in implementing the described embodiments.

23 Fig. 2 is a schematic diagram of a system that can be utilized to capture
24 both structural information and reflectance information of a subject's face at the
25 same time.
